Abstract

The physical science in its present phase focuses on *five* fundamental areas, namely, time, space, energy, matter and conveyed information. This form of science could be categorized as 'local' science. On the other hand, there supposedly exists another science of *five* distinguished members of the nonlocal family. Namely they are consciousness, mind, life-principle, self and information. Each member of the nonlocal family supposedly follows a standard operative procedure (SOP) of action and interaction. Local science is a creation of mind. Nonlocal science is creation of consciousness. The observation which points towards a *connection* between them is the fact that nonlocal 'identities' in different phases, although, work beyond Planck's scale of measurement their effects are seen in the local domain. The *confrontation* of the two sciences occurs in the domain reigned by the phenomenon of death. The *unity* of the two domains, therefore, could be found out in the science of transcendence of death which could unwind the proposed intertwining triple helix formed by *life-principle*, *information* and *mind*. It is, however, yet to be known how the members of the nonlocal family can behave as if in a confined state.
